

Budget Optimization Module

The Budget Optimization Module is designed to help users make the best possible car selection within their financial limits. This module focuses on analyzing user budget constraints and suggesting the most suitable and value-for-money car options. When a user enters a budget, the system identifies cars that fall within that range and ranks them based on performance, features, fuel efficiency, and maintenance cost. It ensures that users get the best possible option without exceeding their budget. Additionally, the module suggests slightly higher-priced alternatives that offer significantly better value or features. This helps users make smarter decisions by considering upgrade options. The module also highlights “best value for money” cars by comparing price with features and long-term cost benefits. It works closely with the recommendation engine and car database to provide accurate and optimized results. Future enhancements may include financial planning tools such as loan eligibility checks and dynamic EMI suggestions. Technologies Used: - HTML: For capturing user budget input. - CSS: For styling budget-related UI components. - JavaScript: For dynamic updates and interaction. - Python (Flask): For implementing optimization logic and backend processing. - Database (MongoDB/MySQL): For retrieving and analyzing car data. Overall, the Budget Optimization Module ensures users get the maximum value within their budget, making the car selection process more practical and efficient.
