

Car Comparison Module

The Car Comparison Module allows users to compare multiple cars side by side to make informed decisions **quickly** and efficiently. This module is designed to present key specifications and features of different cars in a structured comparison format. Users can select 2–3 cars and view a detailed comparison based on parameters such as price, mileage, engine power, fuel type, safety ratings, maintenance cost, and additional features. This helps users quickly identify the differences and choose the best option. The module ensures that all comparison data is displayed clearly in tabular format, making it easy to understand even for non-technical users. It eliminates the need for manual comparison across multiple platforms. This module is integrated with the car database to fetch real-time data and ensures that the comparison reflects the most updated information. It also works closely with the recommendation and filtering modules to allow seamless navigation. Future enhancements may include graphical comparisons, highlighting best values, and AI-based comparison suggestions.

Technologies Used:

- HTML: For structuring comparison tables and UI layout.
- CSS: For styling and making the comparison visually clear and responsive.
- JavaScript: For dynamic selection and updating comparison results.
- Python (Flask): For backend logic, handling requests, and fetching comparison data.
- Database (MongoDB/MySQL): For retrieving car details used in comparison.

Overall, the Car Comparison Module simplifies the decision-making process by presenting all critical information in one place, helping users choose the most suitable car efficiently.
